# Probit Regression for Large Data Sets via Coresets

Alexander Munteanu Simon Omlor Christian Peters

TU Dortmund University, Germany

December 18, 2021

#### Data:

- n observations:  $x_1, \ldots, x_n \in \mathbb{R}^d$
- with n labels:  $y_1, \ldots, y_n \in \{-1, 1\}$

#### Data:

- n observations:  $x_1, \ldots, x_n \in \mathbb{R}^d$
- with *n* labels:  $y_1, ..., y_n \in \{-1, 1\}$

#### Model:

- $y_1, \ldots, y_n$  are realizations of  $Y_1, \ldots, Y_n$
- $Y_i \sim Bernoulli(\pi_i), \quad \pi_i = \Phi(x_i^T \beta)$
- $\Phi(\cdot)$  is cdf of standard normal distribution

#### Data:

- n observations:  $x_1, \ldots, x_n \in \mathbb{R}^d$
- with *n* labels:  $y_1, \ldots, y_n \in \{-1, 1\}$

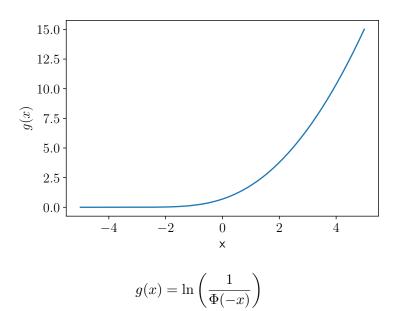

#### Model:

- $y_1, \ldots, y_n$  are realizations of  $Y_1, \ldots, Y_n$
- $Y_i \sim Bernoulli(\pi_i), \quad \pi_i = \Phi(x_i^T \beta)$
- $\Phi(\cdot)$  is cdf of standard normal distribution

### Loss function (negative log-likelihood):

$$f(\beta) = \sum_{i=1}^{n} \ln \left( \frac{1}{\Phi(y_i x_i^T \beta)} \right)$$

### The Probit Loss

#### Problems with large datasets:

- Data doesn't fit into main memory
- Limited access to the data (e.g. data streams)

#### Problems with large datasets:

- Data doesn't fit into main memory
- Limited access to the data (e.g. data streams)

### Scenarios where this can happen:<sup>1</sup>

- Sensor data from mobile devices, cameras, ...
- Internet logs
- Financial data

<sup>&</sup>lt;sup>1</sup>see e.g. [Feldman et al., 2020]

#### Problems with large datasets:

- Data doesn't fit into main memory
- Limited access to the data (e.g. data streams)

### Scenarios where this can happen:<sup>1</sup>

- Sensor data from mobile devices, cameras, ...
- Internet logs
- Financial data

# Conventional optimization algorithms become inefficient!

 $<sup>^{1}</sup>$ see e.g. [Feldman et al., 2020]

Select only a small subset (coreset) of the data!

 $\Rightarrow$  Fit the model on the coreset.

#### Select only a small subset (coreset) of the data!

 $\Rightarrow$  Fit the model on the coreset.

#### Challenges:

- Results on coreset must be close to results on original data
   Need theoretical guarantees!
- $\bullet$  Coreset must be significantly smaller than original data
  - $\Rightarrow$  Otherwise useless!

#### Select only a small subset (coreset) of the data!

 $\Rightarrow$  Fit the model on the coreset.

#### Challenges:

- Results on coreset must be close to results on original data
   Need theoretical guarantees!
- Coreset must be significantly smaller than original data
  - ⇒ Otherwise useless!

Main Goal: Develop efficient coreset construction algorithms!

The coresets we want...

### The coresets we want...

### (1) ...approximate the data well:

- Let  $f(\beta)$  be the original loss and  $\tilde{f}(\beta)$  be the loss on the coreset
- Then for  $\epsilon > 0$  and for all  $\beta \in \mathbb{R}^d$  we want:

$$(1 - \epsilon)f(\beta) \le \tilde{f}(\beta) \le (1 + \epsilon)f(\beta)$$

• This criterion will guarantee our approximation quality!

### The coresets we want...

### (1) ...approximate the data well:

- Let  $f(\beta)$  be the original loss and  $\tilde{f}(\beta)$  be the loss on the coreset
- Then for  $\epsilon > 0$  and for all  $\beta \in \mathbb{R}^d$  we want:

$$(1 - \epsilon)f(\beta) \le \tilde{f}(\beta) \le (1 + \epsilon)f(\beta)$$

• This criterion will guarantee our approximation quality!

### (2) ...are significantly smaller than our data:

- Coreset sizes logarithmic in n would be a great success
- Given a dataset with n=1,000,000,000 observations,  $\log(n) \leq 21$
- Even better: Independent of n!

# Our first obstacle

### Our first obstacle

#### Not every data set allows for small coresets.

• Shown in [Munteanu et al., 2018] for logistic regression, but proof is similar for probit regression

### Our first obstacle

#### Not every data set allows for small coresets.

• Shown in [Munteanu et al., 2018] for logistic regression, but proof is similar for probit regression

#### $\Rightarrow$ Need to restrict the class of data sets under study!

• Slightly adapt the concept of  $\mu$ -complexity from [Munteanu et al., 2018] to probit regression

 $\mu$  is a useful parameter introduced by [Munteanu et al., 2018]:

$$\mu = \sup_{\beta \in \mathbb{R}^d \setminus \{0\}} \frac{\sum_{y_i x_i^T \beta > 0} (x_i^T \beta)^2}{\sum_{y_i x_i^T \beta < 0} (x_i^T \beta)^2}$$

 $\mu$  is a useful parameter introduced by [Munteanu et al., 2018]:

$$\mu = \sup_{\beta \in \mathbb{R}^d \setminus \{0\}} \frac{\sum_{y_i x_i^T \beta > 0} (x_i^T \beta)^2}{\sum_{y_i x_i^T \beta < 0} (x_i^T \beta)^2}$$

Finite  $\mu$ , i.e.  $\mu$ -complexity ensures:

- That the data is not linearly separable
- That the optimum of the loss function exists and is unque

 $\mu$  is a useful parameter introduced by [Munteanu et al., 2018]:

$$\mu = \sup_{\beta \in \mathbb{R}^d \setminus \{0\}} \frac{\sum_{y_i x_i^T \beta > 0} (x_i^T \beta)^2}{\sum_{y_i x_i^T \beta < 0} (x_i^T \beta)^2}$$

Finite  $\mu$ , i.e.  $\mu$ -complexity ensures:

- That the data is not linearly separable
- That the optimum of the loss function exists and is unque

We show how  $\mu$  can be used to find small coresets!

How to tackle coreset construction?

Idea: Use random sampling of observations!

#### How to tackle coreset construction?

Idea: Use random sampling of observations!

#### Problem: Which sampling distribution to use?

- Uniform equal probability sampling is not a good idea
- It is known to fail when the data has outliers
- $\Rightarrow$  We need to give "important" observations a higher priority

### How to tackle coreset construction?

Idea: Use random sampling of observations!

### Problem: Which sampling distribution to use?

- Uniform equal probability sampling is not a good idea
- It is known to fail when the data has outliers
- $\Rightarrow$  We need to give "important" observations a higher priority

Our approach: Use importance sampling based on the sensitivity<sup>2</sup> of each observation!

<sup>&</sup>lt;sup>2</sup>see [Langberg and Schulman, 2010]

# The Sensitivity Framework

### The Sensitivity Framework

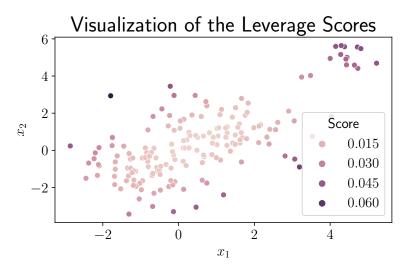

- Well known algorithmic framework for coreset construction via importance sampling introduced by [Feldman and Langberg, 2011].
- The sensitivity is the worst-case importance of an observation
- Sampling proportionally to upper bounds on the sensitivities can lead to small coresets
- $\Rightarrow$  Need to derive tight upper bounds!

# The Sensitivity Framework

- Well known algorithmic framework for coreset construction via importance sampling introduced by [Feldman and Langberg, 2011].
- The sensitivity is the worst-case importance of an observation
- Sampling proportionally to upper bounds on the sensitivities can lead to small coresets
- ⇒ Need to derive tight upper bounds!

We show that the statistical leverage scores can be used to bound the sensitivities of high-loss points!

# Statistical Leverage Scores

#### First pass: Approximate the leverage scores

• Use sketching techniques by [Clarkson and Woodruff, 2017] to approximate the leverage scores

### First pass: Approximate the leverage scores

• Use sketching techniques by [Clarkson and Woodruff, 2017] to approximate the leverage scores

### Second pass: Draw the random sample

• Use a reservoir sampler, e.g. by [Chao, 1982]

### First pass: Approximate the leverage scores

• Use sketching techniques by [Clarkson and Woodruff, 2017] to approximate the leverage scores

### Second pass: Draw the random sample

• Use a reservoir sampler, e.g. by [Chao, 1982]

Coreset size: 
$$O\left(\frac{\mu d^2}{\epsilon^2}\right)$$
, independent of  $n!$ 

# Second Algorithm: Online Leverage Score Sampling

# Second Algorithm: Online Leverage Score Sampling

 $\begin{tabular}{ll} \textbf{Problem:} First algorithm needs two passes. \end{tabular}$ 

## Second Algorithm: Online Leverage Score Sampling

**Problem:** First algorithm needs two passes.

**Solution:** Online approximation of the leverage scores

- Use approximation techniques by [Chhaya et al., 2020]
- Increases coreset size by a factor of  $\log(\sigma_{max})$ 
  - $\sigma_{max}$  is largest singular value of the data matrix
- Needs  $O(d^2)$  update time

### Second Algorithm: Online Leverage Score Sampling

**Problem:** First algorithm needs two passes.

**Solution:** Online approximation of the leverage scores

- Use approximation techniques by [Chhaya et al., 2020]
- Increases coreset size by a factor of  $\log(\sigma_{max})$ 
  - $\sigma_{max}$  is largest singular value of the data matrix
- Needs  $O(d^2)$  update time

Requires only one pass over the data set!

# Goal: Compare our algorithms to uniform random sampling

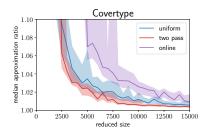

• Show that coreset construction is worth the effort

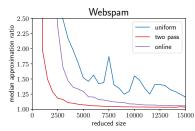

# Goal: Compare our algorithms to uniform random sampling

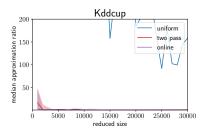

• Show that coreset construction is worth the effort

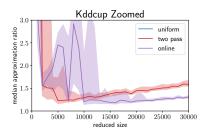

#### Use approximation ratio for evaluation:

- Let  $\tilde{f}(\beta)$  be the loss function on the coreset and let  $f(\beta)$  be the original loss
- Let  $\beta^{opt}$  be the solution of the original problem
- Optimize  $\tilde{f}(\beta)$  to find solution  $\tilde{\beta}$  of the reduced problem
- Compute ratio  $\frac{f(\tilde{\beta})}{f(\beta^{opt})}$

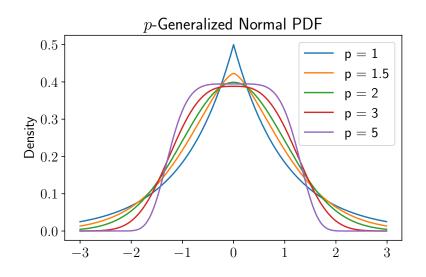

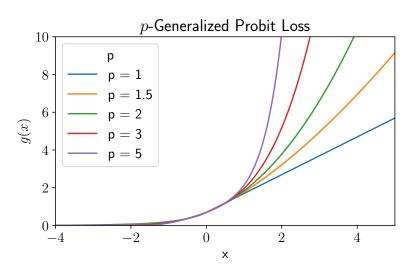

#### Extensions – p-Generalized Probit Model<sup>3</sup>

 $<sup>^3 \</sup>mathrm{See}$  [Kalke and Richter, 2013] for a definition of the p-generalized normal distribution

$$g(x) = \ln\left(\frac{1}{\Phi_p(-x)}\right)$$

Three adaptations are required:

(1) Need to adapt  $\mu$ :

$$\mu = \sup_{\beta \in \mathbb{R}^d \setminus \{0\}} \frac{\sum_{y_i x_i^T \beta > 0} |x_i^T \beta|^p}{\sum_{y_i x_i^T \beta < 0} |x_i^T \beta|^p}$$

Three adaptations are required:

(1) Need to adapt  $\mu$ :

$$\mu = \sup_{\beta \in \mathbb{R}^d \setminus \{0\}} \frac{\sum_{y_i x_i^T \beta > 0} |x_i^T \beta|^p}{\sum_{y_i x_i^T \beta < 0} |x_i^T \beta|^p}$$

(2) Need to use *p*-generalized leverage scores

Three adaptations are required:

(1) Need to adapt  $\mu$ :

$$\mu = \sup_{\beta \in \mathbb{R}^d \setminus \{0\}} \frac{\sum_{y_i x_i^T \beta > 0} |x_i^T \beta|^p}{\sum_{y_i x_i^T \beta < 0} |x_i^T \beta|^p}$$

- (2) Need to use *p*-generalized leverage scores
- (3) Need to adapt the sketching techniques

Three adaptations are required:

(1) Need to adapt  $\mu$ :

$$\mu = \sup_{\beta \in \mathbb{R}^d \setminus \{0\}} \frac{\sum_{y_i x_i^T \beta > 0} |x_i^T \beta|^p}{\sum_{y_i x_i^T \beta < 0} |x_i^T \beta|^p}$$

- (2) Need to use *p*-generalized leverage scores
- (3) Need to adapt the sketching techniques

Coreset size: 
$$\begin{cases} O\left(\frac{\mu d^p}{\epsilon^2}\right), & for \ p \in [1,2) \\ O\left(\frac{\mu d^{2p}}{\epsilon^2}\right), & for \ p \in (2,\infty) \end{cases}$$

- (1) Enabled scalable maximum likelihood estimation of probit models on large datasets and data streams
  - Based on fast coreset construction algorithms and modern sketching techniques

- (1) Enabled scalable maximum likelihood estimation of probit models on large datasets and data streams
  - Based on fast coreset construction algorithms and modern sketching techniques
- (2) Demonstrated that our methods outperform standard uniform sampling
  - By conducting experiments on well known real-world datasets

- (1) Enabled scalable maximum likelihood estimation of probit models on large datasets and data streams
  - Based on fast coreset construction algorithms and modern sketching techniques
- (2) Demonstrated that our methods outperform standard uniform sampling
  - By conducting experiments on well known real-world datasets
- (3) Introduced the *p*-generalized probit model as a flexible framework for modeling binary data
  - Enables you to control the tail behavior of the distribution
